

1                   DISTANCE MEASURING DEVICE

2

## 3     Background Information

4

5     The present invention is directed to a distance measuring device according to the  
6     definition of the species of Claim 1.

7

8     A distance measuring device which represents the general class is known from  
9     DE 198 11 550 C2, with which a plurality of signals at different frequencies is  
10    produced by a single oscillator by dividing and filtering out harmonic frequencies.

11

## 12    Advantages of the Invention

13

14    The present invention is directed to a distance measuring device, in particular a  
15    laser distance measuring device, with at least one oscillator which produces a  
16    basic signal at a fundamental frequency, and a first circuit device which produces  
17    a first signal at a frequency which is higher than the fundamental frequency. It is  
18    proposed, according to the present invention, that the first circuit device include  
19    at least one PLL circuit and at least one VCO circuit.

20

21    A distance measuring device with a circuit device of this nature offers the  
22    advantage that the first frequency of the first signal produced by the circuit device  
23    can be much higher than the frequency of a signal which is suitable for use for  
24    the distance measuring device, and the first signal can be obtained by filtering a  
25    harmonic vibration and by amplification. The requirements on the phase  
26    resolution for achieving a certain measurement accuracy are therefore reduced,  
27    and a higher level of accuracy is attainable. A further advantage lies in the fact  
28    that the first frequency can be produced digitally, and no measurement frequency  
29    requirements due to filter elements need be taken into consideration. The  
30    present invention also offers the advantage that the circuit device functions

1 without filter elements, including the associated adapter network and  
2 amplification circuits. Costs can be spared as a result.

3

4 A PLL ("phase locked loop") circuit and a VCO ("voltage-controlled oscillator")  
5 circuit are sufficiently known in the field of electronics. A PLL circuit compares the  
6 phase position of two signals and outputs a voltage which is a function of the  
7 phase position. A VCO circuit produces a signal at a frequency which is a  
8 function of the voltage input to the VCO circuit. Via the combination of a PLL  
9 circuit and a VCO circuit, a circuit device is therefore attainable with which a  
10 starting frequency produced by the VCO circuit can be adapted to a fundamental  
11 frequency with a high level of accuracy. Very high initial frequencies or starting  
12 frequencies with the same stability as the fundamental frequency of the oscillator  
13 are therefore attainable, whereby starting frequencies of over 1 GHz are  
14 possible. The desired starting frequency of the circuit device is attained by  
15 selecting a suitable VCO circuit, the starting frequency range of which includes  
16 the desired frequency.

17

18 The circuit device can be located directly behind the oscillator, so the basic signal  
19 at the fundamental frequency is forwarded to the PLL circuit. It is also possible,  
20 however, to locate one or more circuits which change the basic signal of the  
21 oscillator between the oscillator and the circuit device. For example, a frequency  
22 divider can be located between the oscillator and the circuit device, which divides  
23 the fundamental frequency produced by the oscillator into one or more lower  
24 frequencies. One or more of the lower starting frequencies of the frequency  
25 divider are forwarded to a circuit device, or a particular first circuit device, which  
26 produces a first signal at a first frequency which is higher than the fundamental  
27 frequency.

28

29 Advantageously, the circuit device includes a frequency divider which is provided  
30 to divide the first frequency. Frequency multiplication is thereby made possible in  
31 a simple manner. The frequency divider is used to divide the starting frequency

1 of the VCO circuit, whereby the starting signal of the frequency divider is input to  
2 the PLL circuit for comparison with the signal which is forwarded directly to the  
3 PLL circuit or indirectly from the oscillator. The frequency divider advantageously  
4 divides the starting frequency of the VCO circuit down to the same frequency  
5 which is forwarded directly to the PLL circuit or indirectly from the oscillator.

6

7 A particularly simple circuit device is obtained by integrating the frequency divider  
8 in the PLL circuit.

9

10 In a preferred embodiment of the present invention, the first circuit device  
11 includes an LC filter which is located downstream from the VCO circuit. An LC  
12 filter of this type has inductance (L) and capacitance (C), and is used to improve  
13 signal quality, e.g., by filtering out harmonic vibrations produced by the circuit  
14 device. In this manner, a substantially sinusoidal starting signal of the first circuit  
15 device is obtained, which permits phase determination with a high level of  
16 accuracy in a subsequent measuring process.

17

18 In a further embodiment of the present invention, the distance measuring device  
19 includes a phase-shifting element which produces a second signal out of the  
20 basic signal, whereby the second signal has a second frequency which is  
21 different from the fundamental frequency, and the second signal is produced by  
22 transferring an input signal between discrete phase positions and whereby a  
23 second circuit device with a PLL circuit and a VCO circuit is located downstream  
24 from the phase-shifting element for producing a third signal at a third frequency  
25 which is higher than the second frequency. The second signal can be produced  
26 indirectly or directly from the basic signal. It is possible, for example, to locate a  
27 further element such as a frequency divider between the oscillator and the  
28 phase-shifting element, and to process the output signal from this further element  
29 using the phase-shifting element. With the second circuit device, the second  
30 signal is processed directly or indirectly after an intermediate signal processing  
31 element such that a third signal at a third and high frequency is produced. The

1 first signal at the first frequency and the third signal at the third frequency are  
2 therefore derived from the basic signal produced by the oscillator; as a result, the  
3 two signals have a stable relationship with each other without any adjustment. As  
4 a result, the advantage can be obtained that the low-frequency mixed product of  
5 the first and third signal is just as stable as the basic signal from the oscillator  
6 and, in fact, without any adjustment. A frequency error between the individual  
7 signals at different frequencies is therefore ruled out, since they all trace back to  
8 a basic signal from the oscillator.

9

10 The phase-shifting element produces the second signal via synthetic, i.e., purely  
11 digital frequency shifting, for example. As a result, even slight frequency  
12 deviations which are due to different sources of the signals, e.g., from a plurality  
13 of oscillators, are effectively avoided. Frequency pairs with closely adjacent and  
14 very high frequencies can be obtained, whereby "closely adjacent" is understood  
15 to mean a frequency difference which cannot be obtained via division from a  
16 starting frequency.

17

18 Advantageously, the first and/or second circuit device is provided to multiply its  
19 input frequency by a non-linear multiple. As a result, a simple evaluation of the  
20 phases of signals with frequencies which are shifted relative to each other can be  
21 achieved.

22

23 Drawing

24

25 Further advantages result from the following description of the drawing. An  
26 exemplary embodiment of the present invention is shown in the drawing. The  
27 drawing, description, and claims contain numerous features in combination. One  
28 skilled in the art will also advantageously consider them individually and combine  
29 them to form further reasonable combinations.

30

1 Figure 1 shows a basic schematic diagram of a distance measuring device which  
2 is configured as a laser distance measuring device. Any signal which does not  
3 stand constantly on one direct-current value is considered hereinbelow to have a  
4 frequency  $f$ . The signal can be sinusoidal, rectangular or sinusoidal or  
5 rectangular only for a limited time. If the signal is rectangular, further frequencies  
6 occur in addition to the fundamental oscillation frequency  $f$ , the further  
7 frequencies being referred to as harmonic oscillations. The underlying theory is  
8 known from mathematics and will not be explained in further detail here.

9

10 If the signal is sinusoidal or rectangular only for a limited time—which is the case,  
11 for example, with signals whose phases are shifted by a constant phase angle in  
12 a regular chronological sequence—the signal is also referred to as having a  
13 frequency  $f$ . In this case, the numerical value  $f$  represents that frequency in the  
14 frequency spectrum with the greatest amplitude. In this case, frequencies can  
15 occur which are not a multiple of the frequency  $f$ . Frequencies of this type are  
16 also referred to hereinbelow as harmonic oscillations.

17

18 Figure 1 shows a basic schematic diagram of a distance measuring device  
19 labelled 10. It includes an optical transmitter 12, e.g., a laser diode, and an  
20 optical receiver 14, e.g., a photodiode. Using optical transmitter 12, a collimated,  
21 visible, continuous-wave laser beam is produced as transmitted signal 16, which  
22 is visible on an object 18, also referred to hereinbelow as the target. Transmitted  
23 signal 16 is reflected by object 18 according to the laws of optics and is received  
24 as received signal 20 by optical receiver 14. Immediately after the target  
25 measurement, transmitted signal 16 is forwarded, as reference signal 16', to  
26 optical receiver 14 via an optical change-over switch 22, e.g., a movable flap.

27

28 A circuit arrangement 24 is provided which controls laser distance measuring  
29 device 10. It includes an oscillator 26, which is configured as a quartz oscillator.  
30 Oscillator 26 provides a fundamental frequency  $f_0$ , from which all frequencies  
31 explained in greater detail hereinbelow for operation of distance measuring

1 device 10 are derived. To increase the unambiguous range of the distance  
2 measurement with distance measuring device 10, the device is operated at a  
3 total of three modulation frequencies for transmitted signal 16. Transmitted signal  
4 16 itself is amplitude-modulated in known fashion. As a result, the received signal  
5 is also amplitude-modulated, in the same manner. Due to the fact that optical  
6 change-over switch 22 is switched over at a known point in time, it can be  
7 unambiguously determined based on the chronological sequence whether the  
8 instantaneous optical received signal came directly from optical change-over  
9 switch 22 or object 18.

10

11 Optical receiver 14 is configured as a known avalanche photodiode and allows a  
12 plurality of frequencies to be mixed simultaneously. The configuration and mode  
13 of operation of an avalanche photodiode of this type are known, so they will not  
14 be discussed in greater detail within the framework of the present description.

15

16 A first switchable frequency divider 28 is assigned to oscillator 26, via which the  
17 frequency  $f_0$  provided by oscillator 26 is capable of being divided down to a  
18 frequency  $f_{10}$ , a frequency  $f_{20}$ , or frequency  $f_{30}$ . Frequencies  $f_{10}$ ,  $f_{20}$ ,  $f_{30}$  can  
19 assume any value which is attainable by dividing fundamental frequency  $f_0$ . In  
20 addition, at least two of the frequencies can be identical.

21

22 A circuit device 30 is located downstream from frequency divider 28, which  
23 produces, out of the signal at frequency  $f_{10}$ , a first signal at a frequency  $f_1$  which  
24 is higher than fundamental frequency  $f_0$ . Circuit device 30 includes a PLL circuit  
25 32 and a VCO circuit 34. A frequency divider 36 is integrated in PLL circuit 32.  
26 VCO circuit 34 is a voltage-controlled oscillator and is designed to output a signal  
27 at frequency  $f_1$  or a frequency which is located in a range around frequency  $f_1$ .  
28 Frequency divider 36 is designed to divide a signal at frequency  $f_1$  down to a  
29 signal in the range of frequency  $f_{10}$ . PLL circuit 32 is a phase-locked loop and is  
30 provided for performing a phase comparison of the signal coming from frequency  
31 divider 36 with the signal of frequency  $f_{10}$  coming from frequency divider 28.

1 Circuit device 30 includes an LC filter 35, which has inductance and capacitance.  
2 LC filter 35 filters out harmonic oscillations produced by circuit device 30 and is  
3 used to improve signal quality.

4

5 The first signal at frequency  $f_1$  and the two other signals at frequencies  $f_2$  and  $f_3$   
6 coming from frequency divider 28 are forwarded via a summing element 38 to  
7 optical receiver 14. Frequency  $f_2$  corresponds to frequency  $f_{20}$  output by  
8 frequency divider 28, and frequency  $f_3$  corresponds to frequency  $f_{30}$ . It is also  
9 possible to direct signals at frequency  $f_{20}$  or frequency  $f_{30}$  output by frequency  
10 divider 28 through a bandpass filter and/or an amplifier, neither of which is  
11 shown, so that frequency  $f_2$  or frequency  $f_3$  need not necessarily correspond to  
12 frequency  $f_{20}$  or  $f_{30}$ . It is also possible to locate circuit device 30 directly behind  
13 oscillator 26, so that the basic signal at fundamental frequency  $f_0$  is used as the  
14 input signal for PLL circuit 32.

15

16 A further switchable frequency divider 28' is assigned to oscillator 26. Frequency  
17 divider 28' includes a digital circuit arrangement, which is configured as phase-  
18 shifting element 40. Signals at frequencies  $f_{10}$ ,  $f_{20}$  and  $f_{30}$  can be applied at the  
19 outputs of frequency divider 28'. These frequencies are transferred by phase-  
20 shifting element 40 at frequency  $f_5$  in their phase. A mixture of a plurality of  
21 frequencies in the frequency spectrum therefore results. At least two of the  
22 frequencies  $f_{10}$ ,  $f_{20}$  and  $f_{30}$  can be identical.

23

24 Circuit device 30' includes a PLL circuit 32' and a VCO circuit 34'. A frequency  
25 divider 36' is integrated in PLL circuit 32'. VCO circuit 34' is designed to output a  
26 signal at frequency  $f_1$  or a frequency which is located in a range around  
27 frequency  $f_1$ . Frequency divider 36' is designed to divide down a signal with  
28 frequency  $f_1$  to a signal in the range of frequency  $f_{10}$ . PLL circuit 32' is provided  
29 to perform a phase comparison of the signal coming from frequency divider 36'  
30 with the signal at frequency  $f_{10}$  coming from frequency divider 28'. Every time  
31 phase-shifting element 40 shifts the phase of the signal at frequency  $f_{10}$  slightly,

1 PLL circuit 32' builds up again, in conjunction with VCO circuit 34', until the signal  
 2 at frequency  $f_{10}$  coming from frequency divider 36' again has the same phase  
 3 position as the signal at frequency  $f_{10}$  coming from frequency divider 28'. In a  
 4 manner analogous to that of circuit device 30, circuit device 30' also includes an  
 5 LC filter 35', which has inductance and capacitance.

6

7 Optical receiver 14 is acted upon in chronological sequence by the optical signals  
 8 listed below under A, and simultaneously with each optical signal, by the  
 9 electrical signal listed under B:

10

List A	List B
Optical signals:	Associated electrical signals:
Target signal 20 at frequency $f_1$	Mixed signal at frequency $f_1$
Target signal 20 at frequency $f_2$	Mixed signal at frequency $f_2$
Target signal 20 at frequency $f_3$	Mixed signal at frequency $f_3$
Reference signal 16' at frequency $f_1$	Mixed signal at frequency $f_1$
Reference signal 16' at frequency $f_2$	Mixed signal at frequency $f_2$
Reference signal 16' at frequency $f_3$	Mixed signal at frequency $f_3$

11

12 As a result, a transformation to an evaluation signal 42 takes place in a known  
 13 manner via mixing. This evaluation signal 42 contains the necessary basic  
 14 information, i.e., the phase angle of target signal 20 relative to an A/D converter  
 15 clock cycle 52 and, chronologically thereafter, the phase angle of reference  
 16 signal 16' relative to A/D converter clock cycle 52. Calculating the difference  
 17 between the two phase angles per measurement frequency results in the  
 18 reference variable, since it is unchanged in all consecutive measurements. The  
 19 result is one phase angle per measurement frequency pair  $f_1-f_1$ ,  $f_2-f_2$  and  $f_3-f_3$ ,  
 20 i.e., a total of three phase angles. The smallest frequency of frequencies  $f_1$ ,  $f_2$ ,  
 21 and  $f_3$  determines the unambiguous range of the entire distance measurement.  
 22 The largest frequency of frequencies  $f_1$ ,  $f_2$ , and  $f_3$  determines the maximum  
 23 possible measurement accuracy at a given measurement time. The frequency of

1    $f_1$ ,  $f_2$ , and  $f_3$  which is located between the smallest and largest frequency is  
2   basically not required. It is used advantageously, however, when the  
3   measurement accuracy of the smallest frequency is not sufficient to place the  
4   measured result of the largest frequency in the correct range. The latter is  
5   necessary to measure distances which are greater than the unambiguous range  
6   of the highest frequency.

7

8   Frequency  $f_3$  is selected to be relatively small, so that a slow A/D converter with  
9   high resolution can be used. Evaluation signal 42 is directed through an anti-  
10   aliasing filter 44 which is a bandpass filter for the evaluation signal at frequency  $f_4$   
11   and, from this, to an amplifier 46 and then an analog-to-digital converter 48.  
12   Converted evaluation signal 42 is forwarded to a microprocessor 50, which  
13   includes the appropriate arithmetic-logic units, memory units, counting units, etc.,  
14   which determine the distance of object 18 from distance measuring unit 10. A/D  
15   converter clock cycle 52 is provided simultaneously via microprocessor 50 to  
16   control analog-to-digital converter 48. Furthermore, a frequency signal  $f_5$  (trigger  
17   signal) from microprocessor 50—the signal being in an at least partially fixed  
18   ratio to A/D converter clock cycle 52—is used to shift frequencies  $f_{10}$ ,  $f_{20}$  and  $f_{30}$   
19   to frequencies  $f'_{10}$ ,  $f'_{20}$ , and  $f'_{30}$ .

20

21   In the exemplary embodiment it is assumed that oscillator 26 produces a basic  
22   signal at a fundamental frequency  $f_0 = 60$  MHz. Frequency divider 28 divides  
23   fundamental frequency  $f_0$  into frequency  $f_{10} = 30$  MHz, frequency  $f_{20} = 15$  MHz,  
24   and frequency  $f_{30} = 1.875$  MHz. Frequencies  $f_{20}$  and  $f_{30}$  are forwarded,  
25   unchanged, as frequencies  $f_2 = 15$  MHz and  $f_3 = 1.875$  MHz to summing element  
26   38. The signal at frequency  $f_{10}$  is input to PLL circuit. The phase position of this  
27   signal is compared with the phase position of a signal coming from frequency  
28   divider 36, whereby the comparison of the phases of the two signals is converted  
29   to an output voltage of PLL circuit 32. This voltage is used as the input variable  
30   for VCO circuit 34, which uses it to produce a signal at frequency  $f_1 = 900$  MHz.  
31   The signal at frequency  $f_1$  is input to frequency divider 36, which divides

1 frequency  $f_1$  of the signal down to frequency  $f_{10}$ . By comparing the phases of the  
2 two signals at frequency  $f_{10}$  coming from frequency dividers 28 and 36 and the  
3 resultant output voltage of PLL circuit 32, VCO circuit 34 is triggered such that  
4 the signal at frequency  $f_1$  output by it has the same stability and accuracy as the  
5 basic signal at fundamental frequency  $f_0$  of oscillator 26.

6

7 Second frequency divider 28' assigned to oscillator 26 divides fundamental  
8 frequency  $f_0$  of 60 MHz down—in a manner similar to that of frequency divider  
9 28—into signals at frequencies  $f'_{10}$ ,  $f'_{20}$  and  $f'_{30}$ , whereby frequencies  $f'_{10}$ ,  $f'_{20}$  and  
10  $f'_{30}$  are digitally shifted by frequency  $f_4$  relative to frequencies  $f_{10}$ ,  $f_{20}$ , and  $f_{30}$ .  
11 Frequency  $f_4$  is 2.929 kHz, so that frequency  $f'_1$ , which is obtained in a manner  
12 similar to that used to obtain frequency  $f_1$ , is 899.997 MHz. Frequency  $f'_2$  is  
13 29.997 MHz, and frequency  $f'_3$  is 1.872 MHz. All frequencies are produced  
14 digitally with the aid of the trigger signal of frequency  $f_5$  of microprocessor 50. In  
15 the exemplary embodiment it is assumed that trigger signal  $f_5$  at frequency  $f_1 =$   
16 900 MHz and frequency  $f_2 = 15$  MHz have exactly the 4-fold frequency of  $f_4$ . With  
17 each clock cycle of the trigger signal at frequency  $f_5 = 11.716$  kHz, the phase of  
18 the signal at frequency  $f_1$  or  $f_2$  is shifted by 90°, so that a shift of 360° at  
19 frequency  $f_4 = 2.929$  kHz takes place. At frequency  $f_3 = 1.875$  MHz, trigger signal  
20  $f_5$  has the 32-fold frequency of  $f_4$ . The frequencies mentioned in this exemplary  
21 embodiment are stated as examples only. Other frequencies are also possible in  
22 other exemplary embodiments, of course.
